# REVISIONS

# Description

AMY 1 was revised from original to REV A to make some minor changes and relax a couple of timing requirements. The AMY 1 chip can run 10 MHz clock instead of 5 MHz and the  $\overline{\text{RESET}}$  input pulse width is required to be 10 clocks period instead of 2 clocks.

Due to the addition of on chip test enhancement (see Appendix III), noise generator enhancement (see Noise RAM initialization format) and pin-out assignment change, the AMY 1 Rev. A was revised to AMY 1 Rev. B.

10. INT/RDY Pin Timing

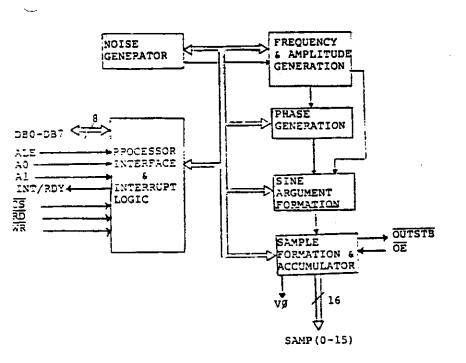

#### 1. GENERAL DESCRIPTION

AMY 1 is a digital, pipeline architectured, additive music synthesizer chip. There are 8 voices maximum assignable with a total of 64 harmonic oscillators, available in groups of two, for voice assignment. AMY 1 has 72 independent, piecewise linear envelope generators: 8 fundamental frequency envelopes and 64 harmonic amplitude envelopes. A complete sound system requires addition of a D/A converter IC (up to 16 bit). To provide higher level commands, the system will generally include a controlling processor such as the Intel 8051 single chip microcomputer.

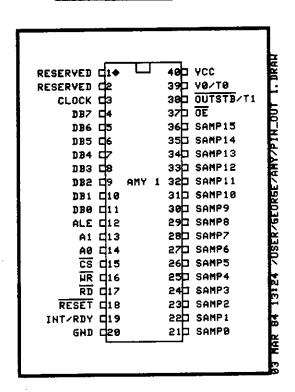

#### 2. FEATURES

- o Single 40 pin DIP
- o 3u HMOS technology
- o Pipeline architecture
- o 10 MHz external clock frequency (maximum)
- o Integrated exponential ROM
- o 1/128 dB harmonic amplitude resolution & 1/64 semitone fundamental frequency resolution
- o Interrupt/Ready pin
- o Bus compatible with multiplexed and non-multiplexed bus microprocessors
- o Full 16 bit digital output width
- o Independent voice mode
- o Adjustable sample rate
- o Programmable noise statistics
- 72 on chip envelope generators
- o Approximately 37,000 transistors

# 5. PIN DESCRIPTION

Pin Name	Type	Pin #	Function
v <sub>cc</sub>	I	40	+5 volt supply (±5%).
GND	I	20	Ground.
RESET	I	18	Reset. When low, performs a master reset on the AMY 1 chip. This signal asynchronously terminates device activity and clears the System Options register, System Control register, Sequencer, Control Counter, Subsample Counter, Phase RAM and Digital Output Word (SAMP bus).
A1-A0	I	13–14	Address lines. Used to select internal AMY 1 registers when not in ALE mode. Al is the most significant bit. Al and AO should be tied to Ground when ALE mode is used.
RD	I	17	Read strobe. Used to transfer contents of selected register onto the data bus lines (DBO-DB7). CS pin must be low to enable the AMY bus drivers.
WR	I	16	Write strobe. Used to load the selected AMY register from the data bus lines (DBO-DB7). CS must be low for the transfer to take place.
CS	I	15	Chip select. When low, the $\overline{RD}$ and $\overline{WR}$ pins are enabled. When high, DB7-DB0 are tri-stated. The only time that AMY drives the data bus (DB7-DB0) is when $\overline{CS} = \overline{RD} = 0$ .
CLK	I	3	10 MHz external clock (divided by 2 internally).
DB7-DB0	1/0	4-11	8 bit, tri-state data bus used to transfer data and commands between AMY 1 and the controlling CPU. DB7 is the most significant bit.

		DEVICE NUMBER	DEVICE NAME	
	COMPANY	C021859	AMY 1	
ATARI Semiconductor Group	CONFIDENTIAL '	DOCUMENT NUMBER D021859	PAGE 6 OF 59	

Pin Name	Type	Pin #	Function
SAMP15-SAMP0	0	36-21	16 bit data bus used to transfer data from AMY 1 to an external D/A converter. SAMP15 is the most significant bit. This bus is tristated unless the OE pin is low. This allows more than one device to share a single D/A converter. These outputs are presented in offset binary code form, i.e. 2's complement.
OUTSTB/T1	0	38	Output strobe. When low, indicates that valid data is on the SAMP bus. (see Section 12.2).
INT/RDY	0	19	Interrupt/Ready. When operating in the READY mode, this pin is high only when AMY 1 is not executing a command. In the INTERRUPT mode, the pin generates a 2 clock period wide pulse when completing a command.
ALE	I	12	Address latch enable. When enabled, latches address information from the DBO and DBl bits of the data bus. The AO and Al pins are grounded when this pin is used. When not in use, ALE should be grounded.
VO/TO	0	39	Voice zero. When operating in the INDIVIDUAL mode, the VO pin will be high during one OUTSTB pulse per sample period. During this particular OUTSTB the data on the SAMP bus is the current sample for Voice O.
ŌĒ	I	37	Output enable. When low, the output SAMP data bus is enabled. When high, the output SAMP data bus is tri-stated.
RESERVED		1, 2	Test Pins. Ground when is use. These two pins are designated for Sentry testing only.

#### FUNCTIONAL DESCRIPTION

#### 6.1 Internal Architecture

AMY 1 consists of 8 major blocks as shown in Figure 1 below.

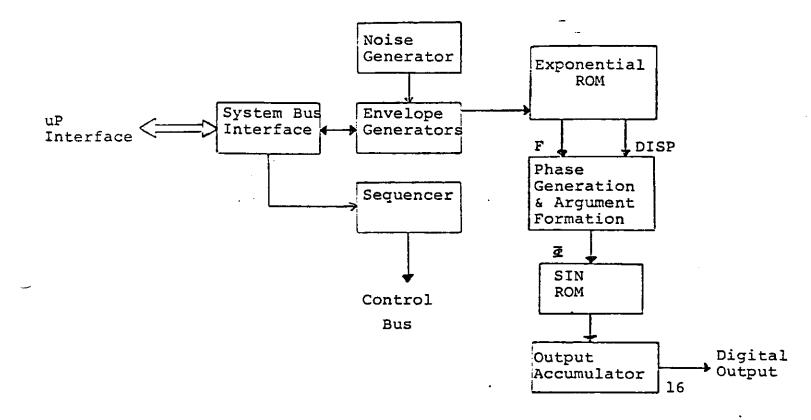

Figure 1. Simplified Block Diagram

The System Bus Interface block provides the user with a standard microprocessor interface. The user sends all commands and passes frequency and amplitude breakpoint data and current values over the "uP Interface" lines (RESET, RD, WR, CS, DB(0-7), ALE, INT/RDY, A1, A0).

The Noise Generator block contains a small RAM, a serial adder, and some associated logic. It generates two different channels of bandlimited white noise simultaneously. Bandwidths are programmable by initialization of the Noise RAM.

ATARI"	CONFIDENTIAL	DOCUMENT NUMBER D021859	PAGE 8 OF 59
Semiconductor Group		<u> </u>	1,722

#### Internal Architecture (continued)

The Envelope Generator block contains the Voice RAM (VRAM), the Harmonic RAM (HRAM) and logic necessary to generate the 72 piecewise linear envelopes (8 fundamental frequency envelopes and 64 harmonic amplitude envelopes). The RAMs maintain a slope value, destination value and current value for each of the 72 envelopes (see Figure 2). The Voice RAM, in addition to slope, destination and current value, contains a 2 bit field for voice type selection. The total Envelope Generator RAM size is  $(64 \times 30) + (21 \times 16)$  bits = 282 bytes.

ATARI Semiconductor Group		DOCUMENT NUMBER D021859	PAGE 9 OF 59	

# Internal Architecture (continued)

The Envelope Generator block also contains the Last Harmonic Pair Flags (32) and an assortment of adders and other logic to generate all AMY envelopes from breakpoint information placed in the HRAM and VRAM by the sequencer under direction of the System Bus Interface command decoder. The Envelope Generator block also contains a Noise Adder. This is used in generating noise based voices.

The Exponential ROM converts the outputs of the 72 envelope generators to a piecewise exponential form for use internally. The ROM permits the AMY user to use decibel units for harmonic amplitude specification and semitone units for fundamental frequency specification. Not only are data widths reduced between the user and AMY, but master amplitude scaling and transposition operations are reduced to simple addition operations in the controlling processor.

The Sequencer block controls all the other blocks. It contains a 7 bit clock period counter and 7 bit subsample counter.

# 6.2 Complete AMY System

A complete sound system requires the addition of a D/A converter chip (up to 16 bit). To provide higher level commands the system will generally include a controlling processor such as the Intel 8051 Single Chip Microcomputer (see Figure 3 below).

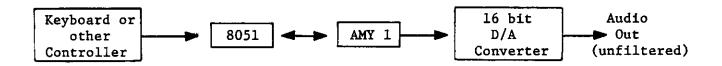

Figure 3. Complete AMY System Block

#### 6.3 Envelope Generation

Envelopes are generated by the on chip AMY 1 envelope generator block. The user may command the generators to make any piecewise linear envelope desired by using a slope and destination scheme. Assume that a particular envelope generator has been previously loaded immediate to zero. By loading two breakpoints (slope-destination pairs) we can generate the following envelope:

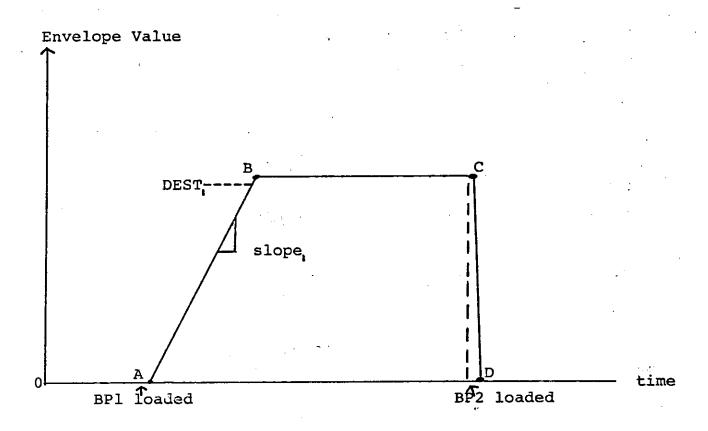

Figure 4. Piecewise linear envelope.

At Point A, BP1 is loaded and the envelope starts rising at a constant slope determined by the "slope" value of BP1. The envelope generator will continue to increase in value until the DEST value is reached. Point B is called a "Free point" since a change in slope has occurred without the user having to load another BP. At Point C, a BP with negative slope and DEST of zero has been loaded into AMY 1. The absolute value of the slope in BP2 is larger than that of BP1, and thus it takes less time for the envelope to "fall" than it did to "rise." Point D is another free point since when the DEST of zero is reached the envelope remains a zero (slope is effectively cleared when the destination is reached).

Semiconductor Group		D021039	PAGE 12 OF 39	

#### 6.3.1 Slope Format

It is desirable to have a very wide range of slopes from nearly instantaneous changes in amplitude or pitch to nearly imperceptible changes in amplitude or pitch. To provide the AMY I user with an adequate range of slopes, an exponential format is used for all AMY I slopes. With this format, and also because all envelopes are exponentiated by the exponential ROM before use in the "oscillator" section of AMY I, a tremendous dynamic range is accomplished (see Appendix II, Musical Specification). The AMY I slope format is:

sign bit	expo	nent	2's	comple	ement	signed	mantissa	
_				•	•	•		
7	6	5	4	3	2	L	U	

Each AMY 1 Harmonic Envelope Generator and Fundamental Frequency (pitch) Envelope Generator has its own slope byte. The sign bit determines whether the slope shall be positive or negative. The mantissa absolute value may range from 1 to 31 (or be 0). The exponent determines how often the mantissa is added (2's complement) to the current value of a particular envelope. If the exponent bits are both one (11), the envelope will be stepwise increased or decreased every other sample period. An exponent of "10" reduces the rate by a factor of 4 to every 8th sample period. An exponent of "01" reduces the rate by another factor of 4 to every 32nd sample. Finally an exponent of "00" implies a rate of every 128 samples. Table 1 shows relative slopes for some sample slope bytes.

1 0 0 1 1 1 1 1 -1 step/128 sample periods = $7.8 \times 10^{-3}$	Slope	Ву	te						Relative Slope (steps/sample)			
1 0 0 1 1 1 1 1 -1 step/128 sample periods = $7.8 \times 10^{-3}$	+/-	E1	EO	M4	мз	M2	Ml	м0				
	0	0	0	0	0	0	0	1	+1 step/128 sample periods = $7.8 \times 10^{-3}$			
0 0 1 0 0 0 1 1 $+2$ store/22 sample periods = 0.09/	1	0	0	1	1	1	1	1	-1 step/128 sample periods = $7.8 \times 10^{-3}$			
0 0 1 0 0 0 1 1 +3 steps/32 sample periods = 0.034	0	0	1	0	0	0	1	1	+3 steps/32 sample periods = 0.094			
0 1 1 1 1 1 1 1 +31 steps/2 sample periods = 15.5	0	1	1	1	1	1	1	1	+31 steps/2 sample periods = $15.5$			
1 1 0 0 0 1 0 0 -28 steps/8 sample periods = -3.5	1	1	0	0	0	1	0	0	-28 steps/8 sample periods = $-3.5$			
1 1 1 0 0 0 0 1 -31 steps/2 sample periods = -15.5	1	1	1	0	0	0	0	1	-31 steps/2 sample periods = $-15.5$			

Table 1. Slope Examples

Notice that the ratio of the maximum to minimum slope is  $R = 15.5/7.8 \times 10^{-3} = 1984$ 

100		DEVICE NUMBER	DEVICE NAME	
<b>│</b>	COMPANY CONFIDENTIAL	C021859	AMY 1	
ATARI Semiconductor Group		DOCUMENT NUMBER D021859	PAGE 13 OF 59	

Slope Format (continued)

To achieve "smooth" pitch and amplitude modulation the "step" must be small. AMY I supports an effective pitch step of 1/2048 of a semitone (approximately a 0.0028% change in frequency) or, in music terms, 0.0488 cents. The amplitude step is 1/128 of a decibel. Both the pitch and amplitude steps were chosen so that pitch and amplitude envelopes will be sensed as "continuous" to the human ear for all AMY I slope values:

Maximum Effective Amplitude Increment =  $\pm$  31/128 dB, Maximum Effective Fundamental Frequency Increment =  $\pm$  31/2048 semitones (Actual Fundamental Frequency Increment =  $\pm$ 1/64 semitones)

The harmonic envelope generators have a dynamic range of 64 dB, therefore, the total amplitude slope dynamic range is:

 $R * 10^{(dB \text{ range}/20)} = 1984 * 10^{64 \text{ dB}/20} = 3.2 * 10^6 \text{ to } 1 \text{ (in volts/sec)}$ 

The pitch (fundamental frequency) has a range of 10 2/3 octaves or 128 semitones. This implies a frequency slope dynamic range of:

 $R * 2^{\text{(octave range)}} = 1984 * 2^{\text{10.667}} = 3.2 * 10^{\text{6}} \text{ to 1}$  (in Hz/sec)

\* 1 cent = 1/100 semitone.

100		DEVICE NUMBER	DEVICE NAME	
<b>/</b>	COMPANY	C021859	AMY 1	
ATARI Semiconductor Group		DOCUMENT NUMBER D021859	PAGE 14 OF 59	

#### 6.3.2 Destination Format

Since all harmonic amplitudes have a 64 dB dynamic range, a single 8 bit byte is used as a destination value for each harmonic amplitude. This leads to an amplitude destination resolution of:

$$\frac{64 dB}{256} = 1/4 dB$$

# Harmonic Amplitude Destination Format and Examples

-	D6	D5	D4	D3	D2	D1	D0
	n	n	n	0	n	Λ	n
_		-	-	-	-	-	
	Ţ	T	Ţ	1	Ŧ	1	ŗ
	0	0	0	0	0	0	1

The Harmonic Amplitude (dB) is a linear function of the Destination value.

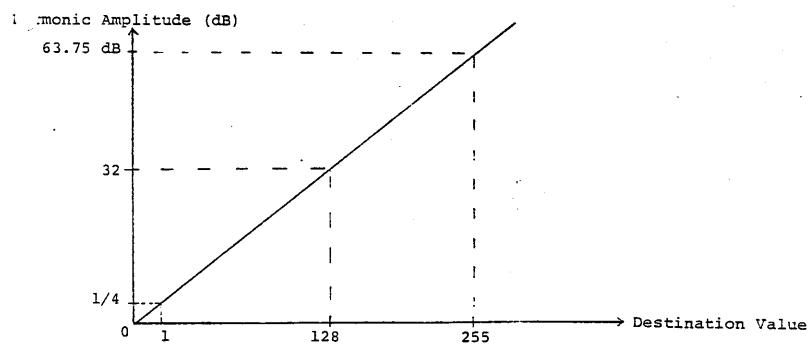

Figure 5. Harmonic Amplitude Destination.

		DEVICE NUMBER	DEVICE NAME
<b>八</b>	COMPANY	C021859	AMY 1
ATARI Semiconductor Group	CONFIDENTIAL	DOCUMENT NUMBER D021859	PAGE 15 OF 59

Destination Format (continued)

Since all Fundamental Frequency envelope generators have a 128 semitone range and a frequency resolution of 1/64 semitones for the Destination is desirable, 13 bits are used in the Frequency destination word.

#### Frequency Destination Format

7	6
Semitone	ATARI Tone
Field	Field

Again, the Fundamental Frequency (semitones) is a linear function of the Destination value.

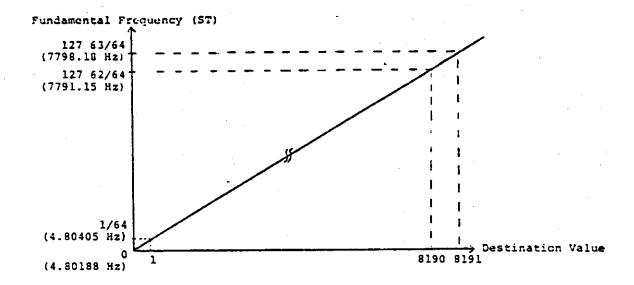

Figure 6. Fundamental Frequency vs. Destination.

Notice that a Destination value of 0000 Hex yields a non-zero frequency and that the frequency resolution around 0 is approximately 0.002 Hz per ATARI tone; at 8191 (or 1FFF Hex), the frequency resolution drops to approximately 7 Hz per ATARI tone. This is desirable and is made possible by the Exponential ROM.

Complete slope tables, computed for a 4 MHz internal clock rate using 64 harmonics, are included in Appendix I.

\* 1 ATARI tone = 1/64 semitone

# 7. REGISTER ORGANIZATION

#### 7.1 AMY 1 Command Set

A command may be sent to AMY 1 by setting  $\overline{CS} = A1 = A\emptyset = 0$ ,  $\overline{RD} = 1$  and  $\overline{WR} = 0$ . The command will be latched internally off the data bus on the trailing edge of the  $\overline{WR}$  pulse. Each 8 bit command contains an opcode from 2 to 5 bits in length, and one or more operands (see Table 2 below).

#### 7.2 RAM and Register Areas

User access to internal RAM and register areas is through 4 registers: 3 data (Reg A (8 bits), Reg B (5 bits), Reg C (8 bits)) and one command register. Figure 7 shows all AMY 1 registers and RAM areas which are manipulated by the AMY 1 command set. To write to AMY 1 (e.g. "Write Fundamental Frequency Breakpoint" command), the user first sets up the proper values in the data registers A, B, and C, then issues the command to AMY 1's Command register.

When reading data from AMY 1 (e.g. "Read Current Fundamental Frequency" command), the user first writes the command to the Command register, then reads the value from the data registers.

Each of the 4 registers is read  $(\overline{RD}=0)$  or written  $(\overline{WR}=0)$  from/to through the data bus lines DBO-DB7 using a unique address on AO-Al (see Table 3). In the case of a read from the Command register, AMY 1's internal bus will appear on DBO-DB7. This has no operational use and is provided for diagnostic purposes.

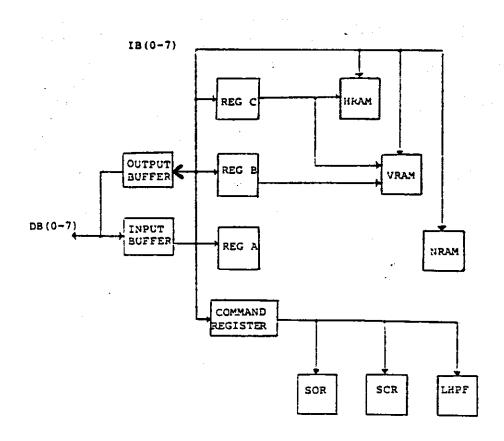

Figure 7. AMY RAM and Register Areas

	T	DEVICE NUMBER	DEVICE NAME
	COMPANY	C021859	AMY 1
ATARI'	CONFIDENTIAL	DOCUMENT NUMBER	10 50
Semiconductor Group	1	D021859	PAGE 18 OF 59

#### 7.3 AMY 1 Data Registers

There are 3 data registers for passing data between the user and AMY 1 internal RAM and Register storage areas. In general, the user loads the registers before sending a 'Write' command to AMY 1 (e.g. "Write Fundamental Frequency Breakpoint" command). Likewise, the user will read data from the registers after sending a 'Read' command to AMY 1 (e.g. "Read Current Fundamental Frequency" command). The registers are named Reg A, Reg B, and Reg C and are always directly accessible to the user since they have unique addresses (see Table 3).

CS	Al	A0	Register Selected
0	0	0	Command (Write only)
0	0	1	
0	1	0	Reg A Reg B (Read or Write)
0	1	1	Reg C).
1	X	X	None

Table 3. Register Selection.

Data bus lines DBO through DB7 are used to pass all data between the user and the  $\underline{AMY}$  1 registers. DBO through DB7 act as inputs (tri-state) unless  $\overline{RD} = \overline{CS} = 0$ , in which case the bus is driven by AMY 1 with the contents of the selected register. If the Command register is selected, the AMY 1 internal bus will be read.

		DEVICE NUMBER	DEVICE NAME
	COMPANY	C021859	AMY 1
ATARI Semiconductor Group	CONFIDENTIAL	DOCUMENT NUMBER D021859	PAGE 19 OF 59

#### 7.4 Other User Accessible Registers and RAM Areas

AMY 1 also contains other internal registers which are loaded by sending various commands to the AMY 1 Command register. These registers are the System Options register, the System Control register, and the Last Harmonic Pair register (see Sections 7.5.5, 7.5.6, and 7.5.8, respectively).

Other AMY I commands pass data to or from AMY I RAM areas. These RAM areas include the Voice RAM, the Harmonic RAM, and the Noise RAM. The VRAM contains the current fundamental frequency, fundamental frequency breakpoint, and the voice type. The HRAM contains the current harmonic amplitude and the harmonic amplitude breakpoint. Initial conditions of the NRAM may be loaded to obtain specific bandlimited white noise statistics.

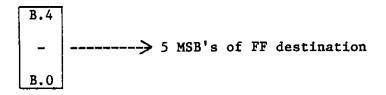

In general, all registers are loaded directly with a single one byte write operation (even the SOR, SCR, and LHPR are loaded from operand data in the command byte). Alternately, RAM areas are read/written indirectly by using Reg A, B, and C as data buffers.

		DEVICE NUMBER	DEVICE NAME
八	COMPANY	C021859	AMY 1
ATARI Semiconductor Group	CONFIDENTIAL	DOCUMENT NUMBER D021859	PAGE 20 OF 59

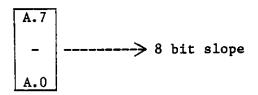

- 7.5 Command Descriptions
- 7.5.1 Write Fundamental Frequency Breakpoint Command (WR FFBP)

Command: 0 0 0 0 1 V2 V1 V0

This command loads a new fundamental frequency slope and destination (FFBP) for the desired voice into the voice RAM. This is done indirectly by loading Reg A, B, and C before the command is issued. V2, V1 and V0 are the voice pointer bits; that is, if V2 = V1 = V0 = 0, then Voice 0's FFBP (slope and destination) will be loaded. If V2 = V1 = 0 and V0 = 1, then Voice 1's FFBP will be modified, etc. The register data format for this command is:

If the slope (Reg A) is zero when the Write FFBP command is issued, the destination will be loaded immediate into the FF current value field of the VRAM. It will remain there until another Write FFBP command is issued.

1111		DEVICE NUMBER	DEVICE NAME	
	COMPANY	C021859	AMY 1	
ATARI Semiconductor Group	CONFIDENTIAL	DOCUMENT NUMBER D021859	PAGE 21 OF 59	

Write Fundamental Frequency Breakpoint (continued)

The slope and destination data are to be loaded into the A, B, and C registers before the WR FFBP command is executed.

# 7.5.2 Write Harmonic Amplitude Breakpoint Command (WR HABP)

Command: 0 1 H5 H4 H3 H2 H1 H0

This command loads a new Harmonic Amplitude slope and destination value (HABP) for the specified harmonic into the Harmonic RAM. The harmonic number is specified by the least significant 6 bits of the command byte (H5-H0). The operation is performed indirectly by loading Reg A and C before the command is issued. Reg B is not used in this command. The register format for this command is:

If the slope byte (Reg A) is zero when the command is issued, the destination will be loaded immediate into the HA current value field of the Harmonic RAM. It will remain at that value until another Write HABP command is issued. This mode is most useful in the "cold Start" software routine immediately after power up of AMY 1, since all harmonic amplitudes may be loaded immediate to zero before the SEQRUN bit is set (see Section 7.5.6).

# 7.5.3 Read Fundamental Frequency Current Value (RD FFCV)

Command: 0 0 0 1 1 V2 V1 V0

This command instructs the AMY 1 sequencer to read, from the Voice RAM, the current value field for the voice specified by the 3 LSB's of the command (V2, V1, V0) and load its contents into the B and C registers where it can be examined by the user. When reading Reg B, bits 7-5 are don't care. Reg A is not used in this command. The register format is as follows:

B.4						
-	 5	MSB's	of	Current	FF	value
B.0						

C.7						
-	> 8	LSB's	of	current	FF	value
C.0

7.5.4 Read Harmonic Amplitude Current Value (RD HACV)

<u> </u>								
Command:	1	1	Н5	H4	Н3	H2	H1	HO

This command instructs the AMY sequencer to read the current value of the harmonic (specified by the 6 LSB of the command byte) into Reg C. The user may then read Reg C for the current amplitude of the specified harmonic. The A and B registers are not used even though Reg B is modified by this command.

# 7.5.5 Write System Options Register (WR SOR)

Command: 0 0 1 0 S03 S02 S01 S00

This command allows the user to select 4 options in AMY 1 operation. The 4 options bits, described below, are loaded directly from the least significant 4 bits of the command byte. Reg A, B, and C are not used in this command. When RESET, bits SO3-SOO default to zero.

S03	S02	501	S00	AMY Mode
			_

1	X	X	X	40 HARMONICS Mode
0	0	0	0	RESET State - Initialize Default
				(ADR pin, READY, SUM and 64 HARMONICS)

Table 4. System Options Register Selection.

#### Notes:

- 1. In ADDRESS PIN mode, Table 4 shows how register selection is accomplished by using the Al and AO pins.
- 2. In ALE mode, the user must put the address information on the data bus (DB1 and DB0) during the ALE strobe time. In <u>multiplexed</u> bus processors, like the 8051, this occurs shortly before the RD or WR strobe times.)

ATARI Semiconductor Group	CONFIDENTIAL	DOCUMENT NUMBER D021859	PAGE 27 OF 59

#### 7.5.6 Write System Control Register (WR SCR)

Command: 0 0 1 1 X X SC1 SC0

This command allows the user to stop the AMY 1 output accumulation process thus holding the output bus to zero, avoiding power up glitches. It also allows the user to place AMY 1 in a special "noise initialize mode." When the WR SCR command is sent, the least significant 2 bits of the command byte are loaded into the SCR. Reg A, B, and C are not used in this command. When RESET, bits SC1-SCO default to zero.

SCl	<del>&gt;</del>	NZINIT Select Noise RAM mode or Last Harmonic Pair mode
SC0	>	SEQRUN Software Reset
sc1	SC0	AMY Mode
X	0	HALT Mode
X	1	SEQUENCER RUN Mode
1	X	Initialize Noise RAM
0	X	NOISE RUN Mode

Table 5. System Control Register Selection.

#### Notes:

- 1. The Sequencer must be running to generate digital sound on the SAMP bus. (In HALT mode, if OE = "0", SAMP (14-0) = "0", SAMP15 = "1")
- 2. In HALT mode, AMY 1 resets the phase of all harmonic oscillators to zero (for selected voices only).
- 3. Initialization of the Noise RAM may be done in the HALT or the SEQUENCER RUN mode.
- 4. When in NOISE RUN mode, both Noise Generators are running and may be selected for use in a particular "Noise Voice" (see Write Voice Type command, Section 7.5.9).

#### 7.5.7 Write Noise RAM Command

Command: 1 0 N5 N4 N3 N2 N1 N0

Note: To use this command, the NZINIT bit in the SCR must be set.

This command loads data from Reg A into the Noise RAM. The address of the Noise RAM is specified in the least significant 6 bits of the command byte. Valid Noise RAM addresses range from 00 to 1D Hex and from 28 to 3F Hex. "Even" addresses in this range correspond to Noise Generator Ø, and the "odd" addresses correspond to Noise Generator 1. See Table on next page for the initialization data format (Noise RAM Initialization Format). The Noise RAM takes up a total of 54 address locations. Loading Noise RAM data to addresses between 1E and 27 Hex is not recommended. Each of the 54 valid Noise RAM locations may be loaded with a 3 bit value. The value is specified by the least significant 3 bits of Reg A. Reg A must be loaded with the proper data before the WR Noise RAM command is issued. See Section 8.2 for the Initialization Flow Chart.

#### 7.5.8 Write Last Harmonic Pair Flag Command

Command: 1 0 HP4 HP3 HP2 HP1 HP0 D0

Note: To use this command, the NZINIT bit in the SCR must first be cleared.

This command allows the user to specify the number of harmonics allocated to each voice. There are a maximum of 8 voices and a maximum of either 40 or 64 harmonics (depending on the state of the 40/64 bit in the SOR). Harmonics must be allocated in groups of 2 or as harmonic pairs. Harmonics 0 and 1 are always assigned to Voice 0. Each pair of harmonics has a Last Harmonic Pair flag which determines whether or not these two harmonics are the last two harmonic of same voice. Therefore, there are 32 such flags. A maximum of 8 of these 32 flags should be set at any one time (since we are limited to 8 voices).

For a single voice of 64 harmonics, all last harmonic pair flags would be set to zero except the last one which is Last Harmonic Pair Flag 31. The HP4-HP0 field in the command byte specifies which flag is to be loaded. The LSB of the command byte (D0) specifies whether the flag is to be cleared or set. The 32 flags power up in a random state and thus all 32 must be set/cleared after power up to define the number of harmonics per voice. Reg A, B, and C are not used by this command.

Harmonic Pair Flags Harmonics Command: Flag 0 HP1 HP0 D<sub>0</sub> HP3 HP2 HP4 1 Data to be Write Last Harmonic loaded 2 Pair Flag into 3 selected Op-Code flag Pointer to Flag of 5 Interest 6 **(60** 30 ८61 (62 31 (63

Example: If all flags are reset except for Flag 3 = Flag 31 = 1, AMY 1 will be set up for 2 voices. Voice 0 will have 8 harmonics (0 through 7) and

Voice 1 will	have 56 harmonice (8 th	DEVACE NUMBER	DEVICE NAME

# 7.5.9 Write Voice Type Command

Command: 0 0 0 1 0 V2 V1 V0

Each voice may be assigned as a Harmonic Voice or as one of two different Noise Source Based Voices. The desired voice is selected by the least significant 3 bits of the command byte. The least significant 2 bits of Reg A determine the "type" of voice desired. Reg A must be loaded before the command is issued according to the following convention (Reg B and C are not used):

A.7	•				
_	<del></del> > 6	MSB's	unused		
A.2 A.1 A.0	> 2	LSB's	determine	voice	type

A.1	A.0	Туре
0	0	Harmonic

# 8. OPERATING PROCEDURE

#### 8.1 Initialization

# 8.1.1 RESET pin and Power up Sequence

Two milliseconds after power up, when spec power supply and clock requirements are met by the AMY 1 interface circuit, the RESET pin may be released (see Figure 8). Alternatively, 2 ms after power up (and before), the RESET pin must be held equal to or less than the  $\overline{\rm V}_{\rm IL}$  spec for the RESET pin (see Figure 9).

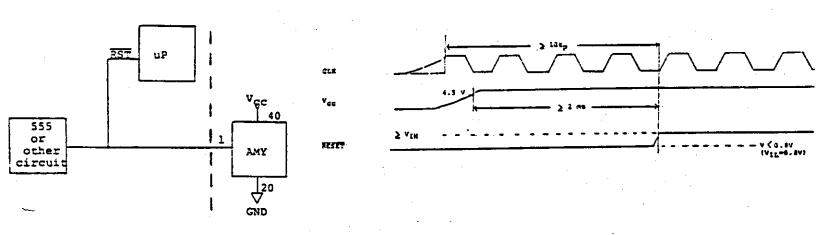

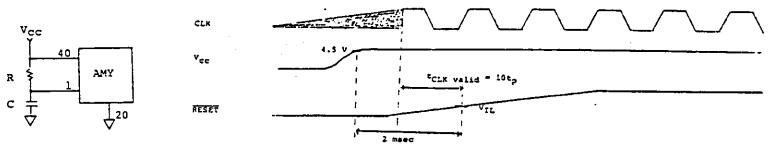

Figure 8. RESET with Standard Up System Reset Circuit

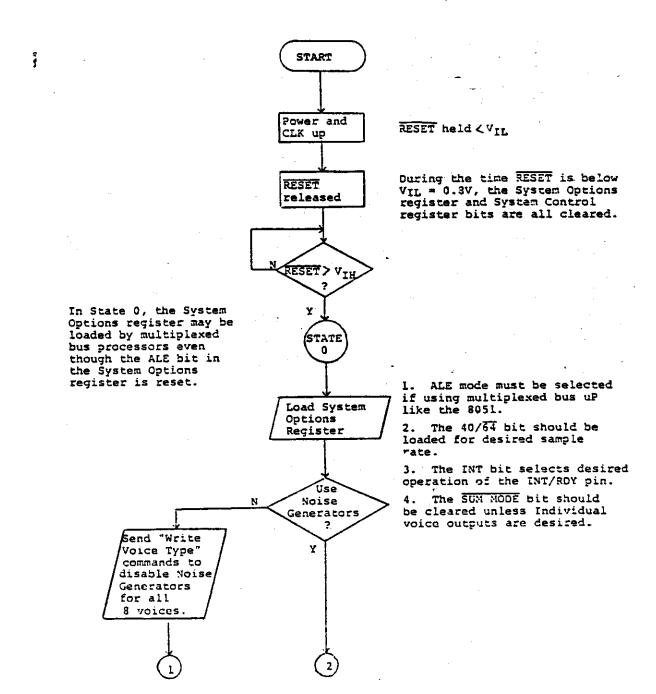

Note: RC requirements depend on  $V_{\text{CC}}$  rise time.

Semiconductor Group		B021039	PAGE 33 OF 39

Although all oscillators are now running and the digital output bus (SAMPO-15) are no longer disabled, the SAMP bus will remain at the "Zero" level since all harmonic amplitudes have been loaded immediate to zero.

Run state

Once the user is in the RUN STATE (State 1), voices may be constructed by first loading the fundamental frequency immediate to some start value and then ramping up/down the Harmonic amplitudes (even the fundamental frequency, if desired). In State 1, an unlimited number of harmonic and fundamental frequency breakpoints may be loaded. Maximum bandwidth of breakpoints is approximately 200,000 BP/sec (essential for peaks in activity). Also, in State 1, the noise generators may be stopped and the Noise RAM reloaded (when the Noise Generator starts running again, the statistics of the noise may change). The number of harmonics per voice may also be modified. The user may change a voice's type, or may read current values of fundamental frequency for any voice or harmonic amplitude for any harmonic. When drastic changes are to be made it is recommended that the user return to State 0 by loading SEQRUN = 0 with the "Write System Control Register Command. In some cases, it may be desirable to "Ramp" all harmonic amplitudes to "zero" before loading SEQRUN = 0 (to avoid a "click").

ATARI Semiconductor Group	CONFIDENTIAL	DOCUMENT NUMBER D021859	PAGE 36 OF 59	

#### 8.3 Summary

Initialization of AMY 1 requires the following steps:

- 1. Loading System Options Register.
  - a. Select 40 or 64 harmonics where the sample rate =  $\frac{1}{2 * \# \text{ harmonics} * t_p}$ ,  $t_p = \text{clock period}$

Example: 64 harmonics with a 4 MHz internal clock rate results in a 31.25 KHz sample rate.

- b. Select ALE or Address Pin mode. If ALE mode is desired, the AO and Al pins should be tied to ground.
- c. Select INT/RDY pin function. If INT bit = 1, the INT/RDY pin will issue a single clock pulse wide interrupt pulse at the completion of all commands. If INT bit = 0, the INT/RDY pin will function as a Ready pin. In the READY mode, the INT/RDY pin will go low (logic 0) immediately upon receipt of a command and return high (logic 1) when the command has been completely executed (see Figure 10).
- d. Select between SUM mode (all voices added together and output once each sample period) or INDIVIDUAL mode (all voices output separately). There will be N output samples per sample period in the INDIVIDUAL mode— N is the number of voices enabled).
- 2. Defining voices using the "Write Last Harmonic Pair Flag" command.
- Clearing all harmonic amplitudes to zero before setting SEQRUN = 1.
- 4. Loading initial conditions into Noise RAM using Write System Control register command and Write Noise RAM command.
- 5. Assigning each voice an initial voice type.

#### APPENDIX I.

Table A shows the 13 bit tone values which correspond to full semitone steps on a piano keyboard. For example, Note A (440 Hz) will be reached if a fundamental frequency envelope reaches a destination value of 5004 Decimal (138C Hex). At a 4 MHz internal clock rate the actual frequency will be 440.04 Hz. The MSB and LSB fields show the Decimal values of the Destination MSB and LSB fields corresponding to the Atari Tone value.

Table B is in the same format as Table A, but the "Note" field was dropped as the values listed are "in between" 2 semitones (or notes on a piano). Table B shows that the actual frequency resolution at 440 Hz is approximately 0.4 Hz (1.5 cents).

Table C shows actual semitone/sec and decibel/sec slopes achieved by various 8 bit slope values. The M (mantissa) and E (exponent) fields are separated to give a feeling for the exponential coding scheme of slope byte. (Data valid for 4 MHz internal clock frequency and 64 harmonic mode).

#### APPENDIX II

#### Musical Specifications

Civen	an	internal	CLK	frequency	٥f	8	MHz	with	64	Harmonics	enabled:
GTAGII	aи	THICKLHUM		Treductica	O.T.	v	LILL	******	vŦ	HOT WONTED	cnapica.

Amplitude Dynamic Range	63.75 dB

Fundamental Frequen	cy Range	4.8 Hz to /.8 KHz
•		$\overline{(}10 \text{ 2/3 octave range)}$

Minimum Fundamental Frequency Slope	5.97 cents*/sec
-------------------------------------	-----------------

Maximum	Fundamental	Frequency	Slope	118 semitones/sec =
				0.05

Maximum Amplitude Increment 31/128 = 0.242 dB

Fundamental Frequency Increment 1/64 semitones =

1.56 cents

Fundamental Frequency Destination Resolution 1/64 semitones =

1.56 cents

Harmonic Amplitude Destination Resolution 1/4 dB

Number of Harmonics 64 (maximum)

Number of Voices 8 (maximum)

Number of Harmonics/Voice Any multiple of 2

Harmonic Distortion 1%

\* 1 cent = 1/100 of a semitone

#### APPENDIX III - Test Mode

The following is a description of test mode for Sentry testing. The system designer should not use this mode for any purpose.

PIN NAME	TYPE	PIN #	FUNCTION
OUTSTBN/T1	1/0	38	When the test pin is low, this pin is an output strobe. If output strobe is low this indicates that valid data is on the sample bus. (See Section 12.2) When the test pin is high, this pin is an input T1 for Sentry testing. (See Test Mode Table)
VO/TO	1/0	39	If the test pin is low, voice zero is an output. When operating in the individual mode, the VO pin will be high during one OUTSTBN pulse per sample period. During this particular OUTSTBN the data on the sample bus is the current sample for Voice O. If the test pin is high, this pin is an input T1 for Sentry testing. (See Test Mode Table)
BOUT/CSYNC (Reserved)	1/0	1	If the test pin is low, this pin will output the noise term serially. If the test pin is high this is an input pin to synchronize the internal clock for Sentry testing only.
TEST (Reserved)	I	2	When test is high, it enables the test mode (See Table **). Ground this pin for normal operation.

#### Test Mode Table

TEST PIN	<u>TO</u>	<u>T1</u>	
0	X	X	Normal Mode
1	0	X	TSTO - Enable 2 Harmonic Counter
1	0	1	TST1 - Enable 8 LSB's of the XROM to the Internal Bus.
1	1	0	TST2 - Enable Slope Reg. to the Internal Bus.

NOTE: When the test pin is enabled, the accumulator is disabled and the data through the pipeline is output directly to the sample bus. In this mode the noise generator is also disabled.
